CRPclustering version 1.0 2018-01-13

Abstract

Clustering is a scientific method which finds the clusters of data and many related methods are traditionally researched for long terms. Bayesian nonparametrics is statistics which can treat models having infinite parameters. Chinese restaurant process is used in order to compose Dirichlet process. The clustering which uses Chinese restaurant process does not need to decide the number of clusters in advance. This algorithm automatically adjusts it. Then, this package can calculate clusters in addition to entropy as ambiguity of clusters.

Introduction

Clustering is a traditional method in order to find clusters of data and many related methods are invented for several decades. The most popular method is called as K-mean(Hartigan 1979). K-mean is an algorithmic way in order to search clusters of data. However its method needs to decide the number of clusters in advance. Therefore if the data is both high dimensions and a complex, deciding the accurate numbers of clusters is difficult and normal bayesian methods are too. For that reason, Bayesian Nonparametric methods are gradually important as computers are faster than ever. In this package, we implement Chinese restaurant process clustering (CRP)(Pitman 1995). CRP can compose infinite dimensional parameters as Dirichlet process(Ferguson 1973). It acts like customers who sit at tables in a restaurant and has a probability to sit at a new table. As a result, Its model always automates clustering. Moreover, we add the method which calculates entropy(Yngvason 1999) of clusters into this package. It can check ambiguity of the result. Then, we explain the clustering model and how to use it in detail. Finally, an example is plotted on a graph.

Background

Chinese Restaurant Process

Chinese restaurant process is a metaphor looks like customers sit at a table in Chinese restaurant. All customers except for x_i have already sat at finite tables. A new customer x_i will sit at either a table which other customers have already sat at or a new table. A new customer tends to sit at a table which has the number of customers more than other tables. A probability equation is given by:

$$\begin{aligned} & p(z_i = k | x_{1:n}, z_{1:n}^{\setminus i}, \alpha, \mu_0, \rho_0, a_0, b_0) \\ &= \begin{cases} p(x_i | \mu_k, \tau) \times \frac{n_k^{\setminus i}}{n-1+\alpha} & \text{if } k \in K^+(Z_{1:n}^{\setminus i}) \\ p(x_i | \mu_k, \tau) \times \frac{\alpha}{n-1+\alpha} & \mu_k \sim N(\mu_0, (\tau\rho_0)^{-1}I) \quad \text{if } k = |K^+(Z_{1:n}^{\setminus i})| + 1 \end{cases} \end{aligned}$$

$n_k^{\setminus i}$ expresses the number of the customers at a table k and α is a concentration parameter.

Markov Chain Monte Carlo Methods for CRP Clustering

Markov chain Monte Carlo (MCMC) methods are algorithmic methods(Liu 1994) to sample from posterior distributions. If conditional posterior distributions are given by models, it is the best way in order to acquire parameters as posterior distributions. The algorithm for this package is given by:

Many iterations continue on below:

- i) Sampling z_i for each i ($i = 1, 2, \dots, n$)

$$p(z_i = k | x_{1:n}, z_{1:n}^{\setminus i}, \alpha, \mu_k, \mu_0, \tau, \rho_0) = \begin{cases} p(x_i | \mu_k, \tau) \times \frac{n_k^{\setminus i}}{n-1+\alpha} \\ p(x_i | \mu_k, \tau) \times \frac{\alpha}{n-1+\alpha} \end{cases} \quad \mu_k \sim N(\mu_0, (\tau \rho_0)^{-1} I)$$

$$z_i \sim \text{Multi}(p(z_i = 1), p(z_i = 2), \dots, p(z_i = \infty))$$

- ii) Sampling μ_k for each k ($k = 1, 2, \dots, \infty$)

$$\mu_k \sim p(\mu_k | x_{1:n}, z_{1:n}, \tau, \mu_0, \rho_0) = N(\mu_k | \frac{n_k}{n_k + \rho_0} \bar{x}_k + \frac{\rho_0}{n_k + \rho_0} \mu_0, (\tau(n_k + \rho_0))^{-1} I)$$

$$\bar{x}_k = \frac{1}{n_k} \sum_{i=1}^n \delta(z_i = k) x_i$$

First several durations of iterations which are called as “burn in” are error ranges. For that reason, “burn in” durations are abandoned.

Cluster Entropy

Entropy expresses ambiguity of clustering. As a result of simulation, data x_i joins in a particular table. From the total numbers n_k of a particular table k at a last iteration, a probability p_k at each cluster k is calculated. The entropy equation is given by:

$$H(x) = - \sum_{k=1}^{\infty} \frac{n_k}{n} \log_2 \frac{n_k}{n}$$

Installation

If download from GitHub, you can use devtools by the commands:

```
> library(devtools)
> install_github("jirotubuyaki/CRPclustering")
```

Once the packages are installed, it needs to be made accessible to the current R session by the commands:

```
> library(CRPclustering)
```

For online help facilities or the details of a particular command (such as the function `crp_gibbs`) you can type:

```
> help(package="CRPclustering")
```

Methods

Calculating Method for Chinese Restaurant Process Clustering

```
> z_result <- crp_gibbs(data, mu=c(0,0), sigma=0.5, sigma_table=12,  
                        alpha=1.0, ro_0=0.1, burn_in=10, iteration=100)
```

This method calculates CRP clustering.

Let's args be:

- data : a matrix of data for clustering. Rows are data i and cols are dimensions of data.
- mu : a vector of center points of data. If data is 3 dimensions, a vector of 3 elements like "c(2,4,7)".
- sigma : a numeric of data variance.
- sigma_table : a numeric of table position variance.
- alpha : a numeric of a CRP concentration rate.
- ro_0 : a numeric of a CRP mu change rate.
- burn_in : an iteration integer of burn in.
- iteration : an iteration integer.

Let's return be:

- z_result : a vector expresses cluster numbers for each data i .

Visualization Method

```
> crp_graph_2d(data, z_result)
```

This method exhibits a two dimensional graph for the method "crp_gibbs".

Let's args be:

- data : a matrix of data for clustering. Rows are data i and cols are dimensions of data.
- z_result : a vector expresses cluster numbers for each data i and the output of the method "crp_gibbs".

Example

Data is generated from three Normal distributions and $\mu_0 = (-1, 1)$, $\mu_1 = (-1.3, -1.3)$, $\mu_2 = (1, -1)$ and $\sigma_0 = 0.3$, $\sigma_1 = 0.02$, $\sigma_2 = 0.3$. The result is plotted as a graph and each data joins in any cluster. The graph is given by below:

Figure 1. CRP clustering result

Conclusions

Chinese restaurant process clustering was implemented and explained how to use it. Computers resources is limited. Computer processing power is the most important problem. And several improvements are planed. Please send suggestions and report bugs to okadaalgorithm@gmail.com.

Acknowledgments

This activity would not have been possible without the support of my family and friends. To my family, thank you for much encouragement for me and inspiring me to follow my dreams. I am especially grateful to my parents, who supported me all aspects.
